

### **Chapter 7: Entity-Relationship Model**

- Design Process
- Modeling
- Constraints
- E-R Diagram
- Design Issues
- Weak Entity Sets
- Extended E-R Features
- Design of the University Database
- Reduction to Relation Schemas
- Database Design

#### Modeling

- A database can be modeled as:
  - a collection of entities,
  - relationship among entities.
- An entity is an object that exists and is distinguishable from other objects.
  - Example: specific person, company, event, plant
- Entities have attributes
  - Example: people have names and addresses
- An **entity set** is a set of entities of the same type that share the same properties.
  - Example: set of all persons, companies, trees, holidays

#### Entity Sets instructor and student

#### instructor\_ID instructor\_name

76766	Crick
45565	Katz
10101	Srinivasan
98345	Kim
7(542	C: 1
76543	Singh

instructor

#### student\_ID student\_name

98988	Tanaka
12345	Shankar
00128	Zhang
76543	Brown
76653	Aoi
23121	Chavez
44553	Peltier

student

#### **Relationship Sets**

A relationship is an association among several entities

#### Example:

44553 (Peltier) <u>advisor</u> 22222 (<u>Einstein</u>) student entity relationship *instructor* entity

A relationship set is a mathematical relation among  $n \ge 2$  entities, each taken from entity sets

$$\{(e_1, e_2, \dots e_n) \mid e_1 \in E_1, e_2 \in E_2, \dots, e_n \in E_n\}$$

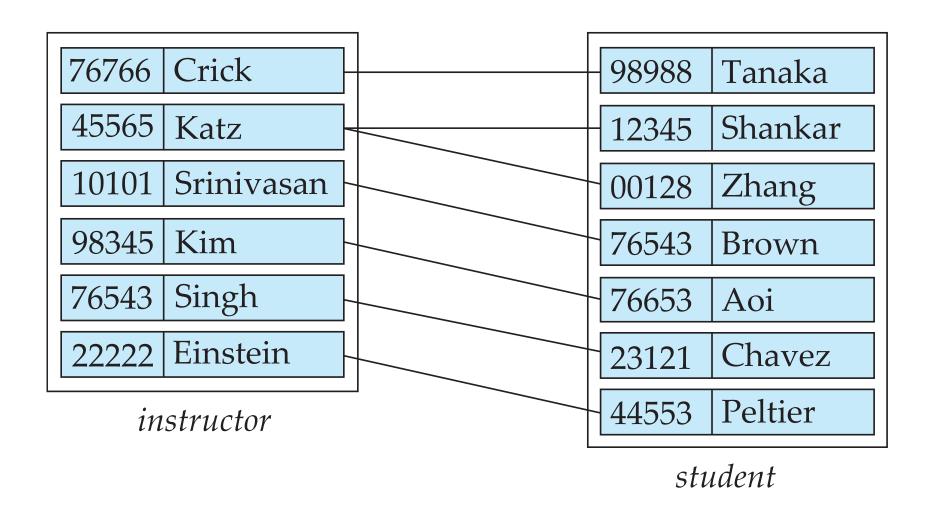

where  $(e_1, e_2, ..., e_n)$  is a relationship

Example:

 $(44553, 22222) \in advisor$ 

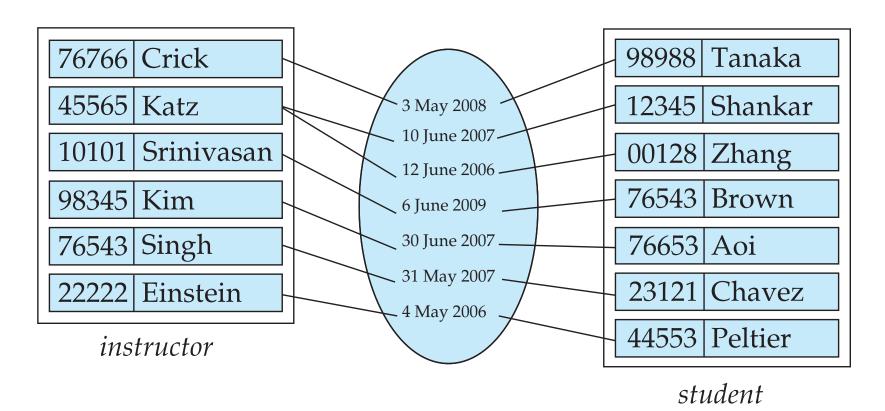

#### Relationship Set advisor

## **Relationship Sets (Cont.)**

- An attribute can also be property of a relationship set.
- For instance, the advisor relationship set between entity sets instructor and student may have the attribute date which tracks when the student started being associated with the advisor

#### Degree of a Relationship Set

#### binary relationship

- involve two entity sets (or degree two).
- most relationship sets in a database system are binary.

- Relationships between more than two entity sets are rare. Most relationships are binary. (More on this later.)
  - Example: *students* work on research *projects* under the guidance of an *instructor*.
  - relationship proj\_guide is a ternary relationship between instructor, student, and project

#### **Attributes**

- An entity is represented by a set of attributes, that is descriptive properties possessed by all members of an entity set.
  - Example:

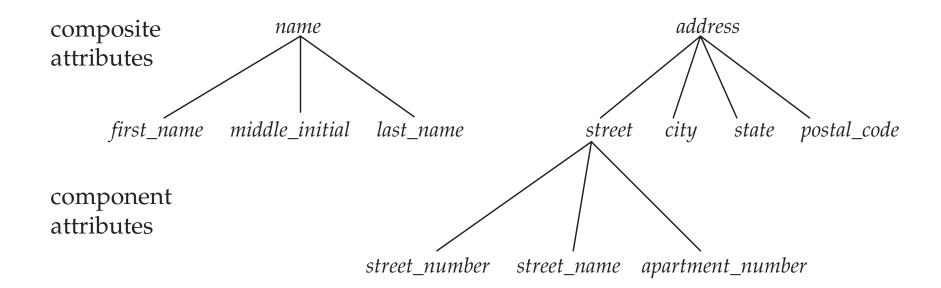

```
instructor = (ID, name, street, city, salary)
course= (course_id, title, credits)
```

- Domain the set of permitted values for each attribute
- Attribute types:
  - Simple and composite attributes.
  - Single-valued and multivalued attributes
    - Example: multivalued attribute: phone\_numbers
  - Derived attributes
    - Can be computed from other attributes
    - Example: age, given date\_of\_birth

NYU School of Engineering

## **Composite Attributes**

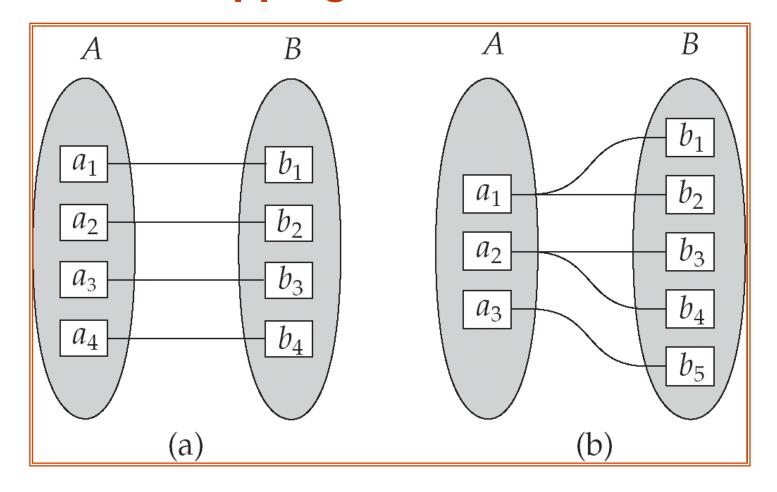

### **Mapping Cardinality Constraints**

- Express the number of entities to which another entity can be associated via a relationship set.
- Most useful in describing binary relationship sets.
- For a binary relationship set the mapping cardinality must be one of the following types:
  - One to one
  - One to many
  - Many to one
  - Many to many

#### **Mapping Cardinalities**

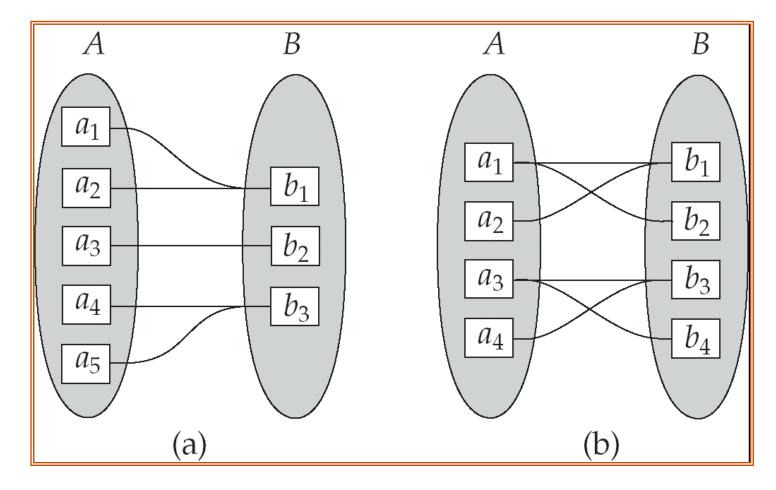

One to one

One to many

Note: Some elements in *A* and *B* may not be mapped to any elements in the other set

#### **Mapping Cardinalities**

Many to one

Many to many

Note: Some elements in A and B may not be mapped to any elements in the other set

### **Keys**

- A super key of an entity set is a set of one or more attributes whose values uniquely determine each entity.
- A candidate key of an entity set is a minimal super key
  - ID is candidate key of instructor
  - course\_id is candidate key of course
- Although several candidate keys may exist, one of the candidate keys is selected to be the primary key.

### **Keys for Relationship Sets**

- The combination of primary keys of the participating entity sets forms a super key of a relationship set.
  - (s\_id, i\_id) is the super key of advisor
  - NOTE: this means a pair of entity sets can have at most one relationship in a particular relationship set.
    - Example: if we wish to track multiple meeting dates between a student and her advisor, we cannot assume a relationship for each meeting. We can use a multivalued attribute though
- Must consider the mapping cardinality of the relationship set when deciding what are the candidate keys
- Need to consider semantics of relationship set in selecting the primary key in case of more than one candidate key

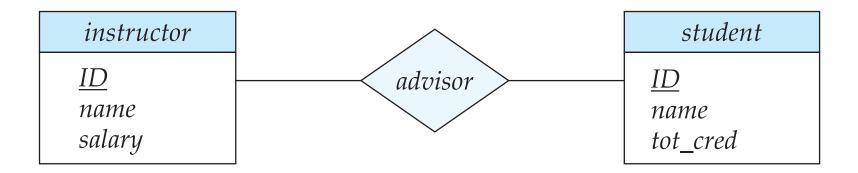

#### **Redundant Attributes**

- Suppose we have entity sets
  - instructor, with attributes including dept\_name
  - departmentand a relationship
  - inst\_dept relating instructor and department
- Attribute dept\_name in entity instructor is redundant since there is an explicit relationship inst\_dept which relates instructors to departments
  - The attribute replicates information present in the relationship, and should be removed from instructor
  - BUT: when converting back to tables, in some cases the attribute gets reintroduced, as we will see.

#### **E-R Diagrams**

- Rectangles represent entity sets.
- Diamonds represent relationship sets.
- Attributes listed inside entity rectangle
- Underline indicates primary key attributes

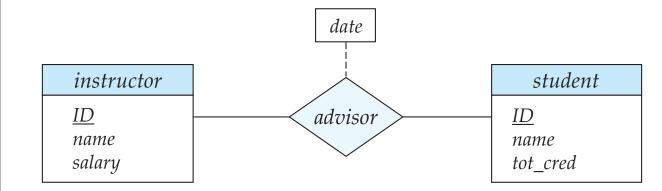

## Entity With Composite, Multivalued, and Derived Attributes

#### instructor

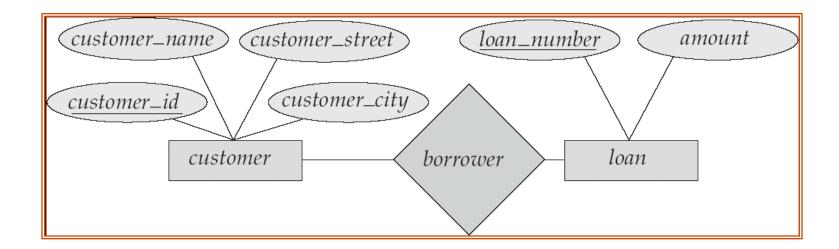

```
\underline{ID}
name
  first_name
   middle_initial
   last name
address
   street
      street number
      street name
      apt_number
   city
   state
   zip
{ phone_number }
date_of_birth
age()
```

#### **Relationship Sets with Attributes**

#### **Alternative Notation: E-R Diagrams**

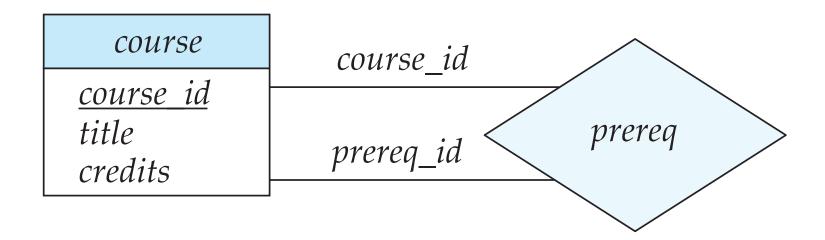

- Used in previous edition of the book
- Same thing otherwise

#### Roles

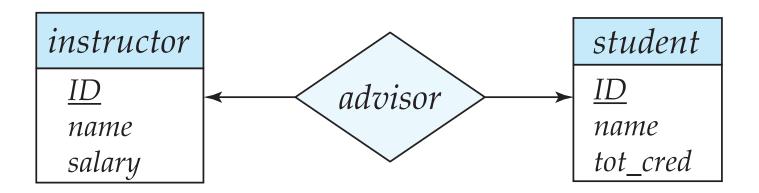

- Entity sets of a relationship need not be distinct
  - Each occurrence of an entity set plays a "role" in the relationship
- The labels "course\_id" and "prereq\_id" are called roles.

#### **Cardinality Constraints**

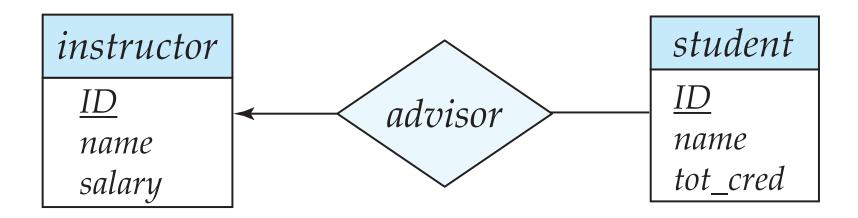

- We express cardinality constraints by drawing either a directed line (→), signifying "one," or an undirected line (—), signifying "many," between the relationship set and the entity set.
- one-to-one relationship between an *instructor* and a *student* 
  - an instructor is associated with at most one student via advisor
  - and a student is associated with at most one instructor via advisor

#### **One-to-Many Relationship**

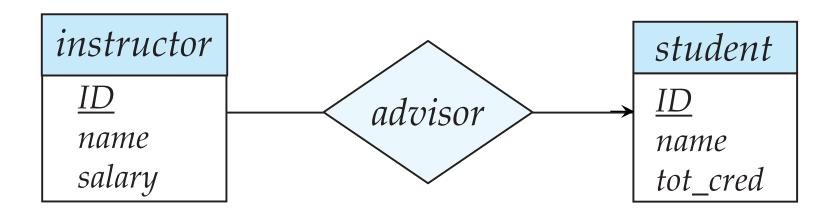

- one-to-many relationship between an *instructor* and a *student* 
  - an instructor is associated with several (including 0) students via advisor
  - a student is associated with at most one instructor via advisor,

#### **Many-to-One Relationships**

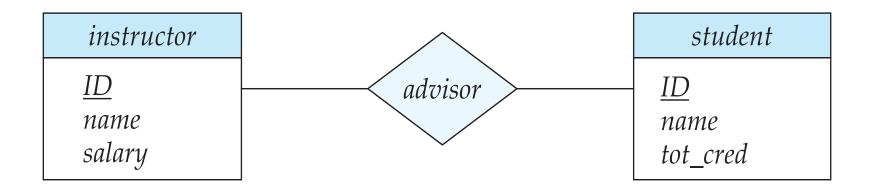

- In a many-to-one relationship between an instructor and a student,
  - an instructor is associated with at most one student via advisor,
  - and a student is associated with several (including 0) instructors via advisor

#### **Many-to-Many Relationship**

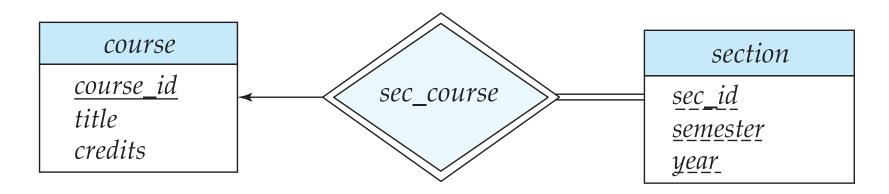

- An instructor is associated with several (possibly 0) students via advisor
- A student is associated with several (possibly 0) instructors via advisor

# Participation of an Entity Set in a Relationship Set

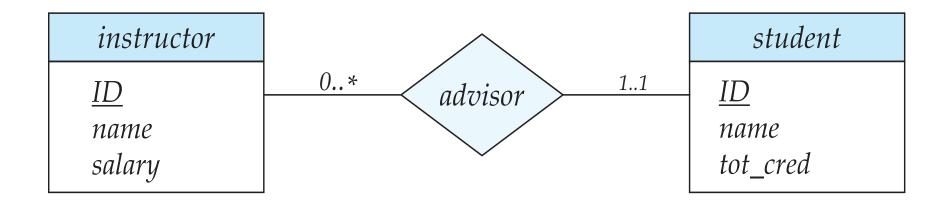

- Total participation (indicated by double line): every entity in the entity set participates in at least one relationship in the relationship set
  - E.g., participation of section in sec\_course is total
    - every section must have an associated course
- Partial participation: some entities may not participate in any relationship in the relationship set
  - Example: participation of instructor in advisor is partial

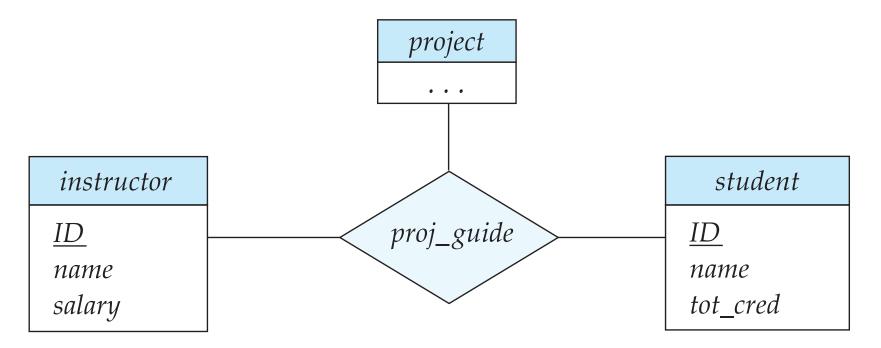

## **Alternative Notation for Cardinality Limits**

Cardinality limits can also express participation constraints

### E-R Diagram with a Ternary Relationship

# Cardinality Constraints on Ternary Relationship

- We allow at most one arrow out of a ternary (or greater degree) relationship to indicate a cardinality constraint
- E.g., an arrow from *proj\_guide* to *instructor* indicates each student has at most one guide for a project
- If there is more than one arrow, there are two ways of defining the meaning.
  - E.g., a ternary relationship R between A, B and C with arrows to B and C could mean
    - 1. each A entity is associated with a unique entity from B and C or
    - 2. each pair of entities from (A, B) is associated with a unique C entity, and each pair (A, C) is associated with a unique B
  - Each alternative has been used in different formalisms.
  - To avoid confusion we outlaw more than one arrow

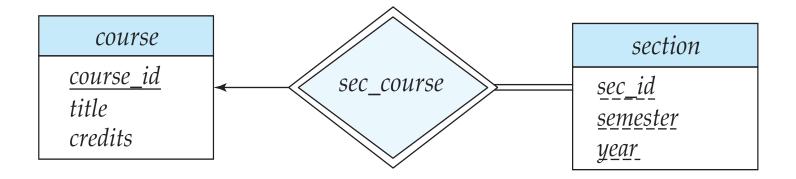

#### **Weak Entity Sets**

- An entity set that does not have a primary key is referred to as a weak entity set.
- The existence of a weak entity set depends on the existence of a identifying entity set
  - It must relate to the identifying entity set via a total, one-tomany relationship set from the identifying to the weak entity set
  - Identifying relationship depicted using a double diamond
- The discriminator (or partial key) of a weak entity set is the set of attributes that distinguishes among all the entities of a weak entity set.
- The primary key of a weak entity set is formed by the primary key of the strong entity set on which the weak entity set is existence dependent, plus the weak entity set's discriminator.

#### Weak Entity Sets (Cont.)

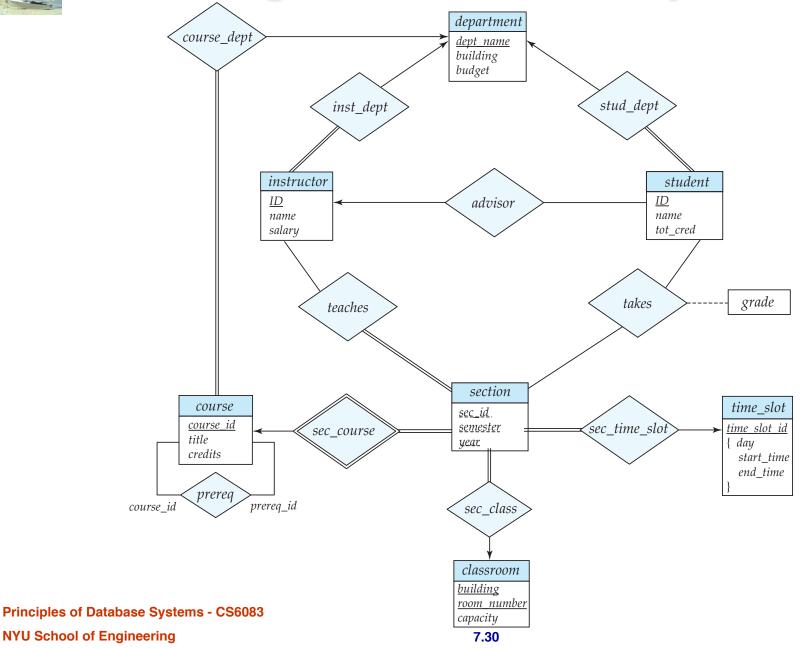

- We underline the discriminator of a weak entity set with a dashed line.
- We put the identifying relationship of a weak entity in a double diamond.
- Primary key for section (course\_id, sec\_id, semester, year)

- Note: the primary key of the strong entity set is not explicitly stored with the weak entity set, since it is implicit in the identifying relationship.
- If course\_id were explicitly stored, section could be made a strong entity, but then the relationship between section and course would be duplicated by an implicit relationship defined by the attribute course\_id common to course and section

## E-R Diagram for a University Enterprise

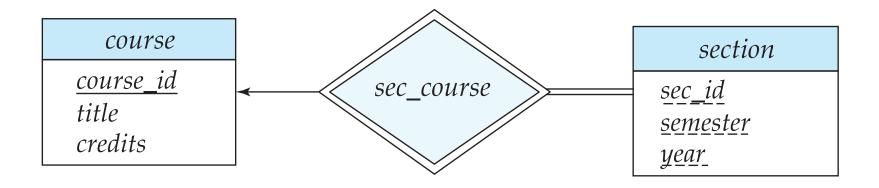

#### **Reduction to Relation Schemas**

- Entity sets and relationship sets can be expressed uniformly as relation schemas that represent the contents of the database.
- A database which conforms to an E-R diagram can be represented by a collection of schemas.
- For each entity set and relationship set there is a unique schema that is assigned the name of the corresponding entity set or relationship set.
- Each schema has a number of columns (generally corresponding to attributes), which have unique names.

# Representing Entity Sets With Simple Attributes

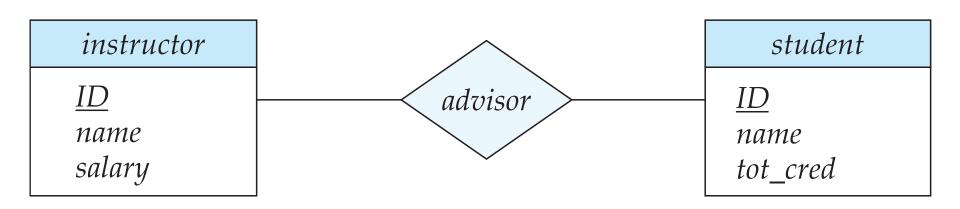

- A strong entity set reduces to a schema with the same attributes student(<u>ID</u>, name, tot\_cred)
- A weak entity set becomes a table that includes a column for the primary key of the identifying strong entity set section (<u>course\_id</u>, <u>sec\_id</u>, <u>sem</u>, <u>year</u>)

#### Representing Relationship Sets

- A many-to-many relationship set is represented as a schema with attributes for the primary keys of the two participating entity sets, and any descriptive attributes of the relationship set.
- Example: schema for relationship set advisor advisor = (s\_id, i\_id)

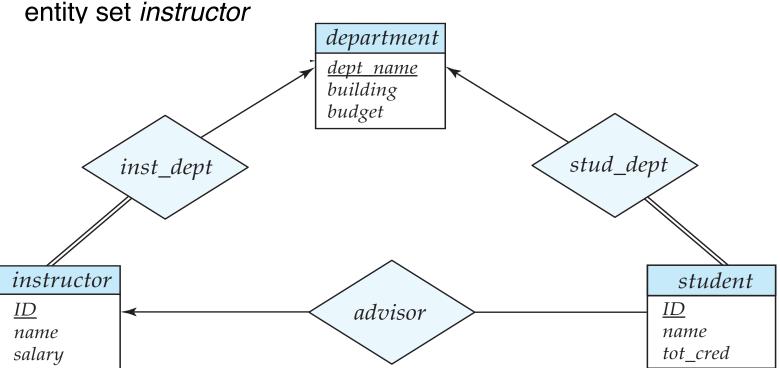

#### **Redundancy of Schemas**

Many-to-one and one-to-many relationship sets that are total on the many-side can be represented by adding an extra attribute to the "many" side, containing the primary key of the "one" side

Example: Instead of creating a schema for relationship set inst\_dept, add an attribute dept\_name to the schema arising from

### Redundancy of Schemas (Cont.)

- For one-to-one relationship sets, either side can be chosen to act as the "many" side
  - That is, extra attribute can be added to either of the tables corresponding to the two entity sets
- If participation is partial on the "many" side, replacing a schema by an extra attribute in the schema corresponding to the "many" side could result in null values
  - Example: Partial participation of student to relationship advisor
- The schema corresponding to a relationship set linking a weak entity set to its identifying strong entity set is redundant.
  - Example: The section schema already contains the attributes that would appear in the sec\_course schema

#### **Composite and Multivalued Attributes**

#### instructor

```
ID
name
  first_name
   middle_initial
   last_name
address
   street
      street_number
      street name
      apt_number
   city
   state
   zip
{ phone_number }
date_of_birth
age()
```

- Composite attributes are flattened out by creating a separate attribute for each component attribute
  - Example: given entity set instructor with composite attribute name with component attributes first\_name and last\_name the schema corresponding to the entity set has two attributes name\_first\_name and name\_last\_name
    - Prefix omitted if there is no ambiguity
- Ignoring multivalued attributes, extended instructor schema is
  - instructor(ID, first\_name, middle\_initial, last\_name, street\_number, street\_name, apt\_number, city, state, zip\_code, date\_of\_birth)

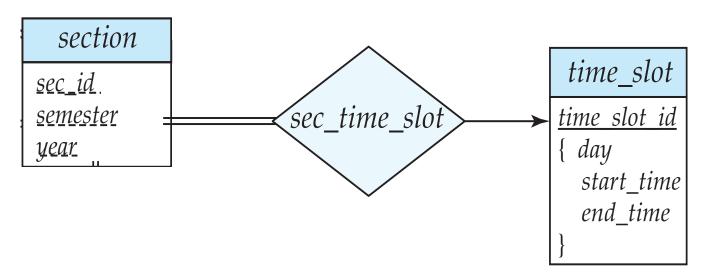

#### **Composite and Multivalued Attributes (Cont.)**

- A multivalued attribute M of an entity E is represented by a separate schema EM
  - Schema EM has attributes corresponding to the primary key of E and an attribute corresponding to multivalued attribute M
  - Example: Multivalued attribute phone\_number of instructor is represented by a schema:
     inst\_phone= ( <u>ID</u>, <u>phone\_number</u>)
  - Each value of the multivalued attribute maps to a separate tuple of the relation on schema EM
    - For example, an *instructor* entity with primary key 22222 and phone numbers 456-7890 and 123-4567 maps to two tuples: (22222, 456-7890) and (22222, 123-4567)

## **Multivalued Attributes (Cont.)**

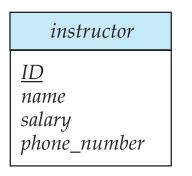

- Special case: entity time\_slot has only one attribute other than the primary-key attribute, and that attribute is multivalued
  - Optimization: Don't create the relation corresponding to the entity, just create the one corresponding to the multivalued attribute
  - time\_slot(time\_slot\_id, day, start\_time, end\_time)
  - Caveat: time\_slot attribute of section (from sec\_time\_slot) cannot be a foreign key due to this optimization

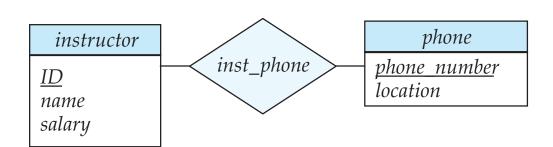

#### **Design Issues**

Use of entity sets vs. attributes

 Use of phone as an entity allows extra information about phone numbers (plus multiple phone numbers)

## **Design Issues (Cont.)**

Use of entity sets vs. relationship sets
Possible guideline is to designate a relationship set to describe an action that occurs between entities

#### **Design Issues (Cont.)**

#### **■** Binary versus n-ary relationship sets

Although it is possible to replace any non-binary (n-ary, for n > 2) relationship set by a number of distinct binary relationship sets, a n-ary relationship set shows more clearly that several entities participate in a single relationship.

#### Placement of relationship attributes

e.g., attribute date as attribute of advisor or as attribute of student

# Binary Vs. Non-Binary Relationships

- Some relationships that appear to be non-binary may be better represented using binary relationships
  - E.g., A ternary relationship parents, relating a child to his/her father and mother, is best replaced by two binary relationships, father and mother
    - Using two binary relationships allows partial information (e.g., only mother being know)
  - But there are some relationships that are naturally non-binary
    - Example: proj\_guide

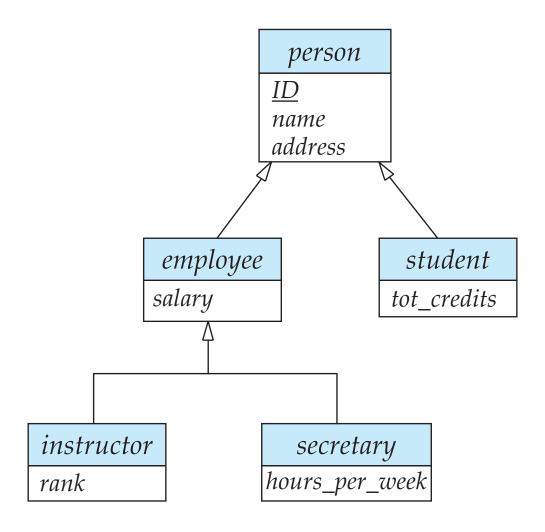

#### **Extended E-R Features: Specialization**

- Top-down design process; we designate subgroupings within an entity set that are distinctive from other entities in the set.
- These subgroupings become lower-level entity sets that have attributes or participate in relationships that do not apply to the higher-level entity set.
- Depicted by a triangle component labeled ISA (E.g., instructor "is a" person).
- Attribute inheritance a lower-level entity set inherits all the attributes and relationship participation of the higher-level entity set to which it is linked.

# **Specialization Example**

#### **Specialization and Generalization**

- A bottom-up design process combine a number of entity sets that share the same features into a higher-level entity set.
- Specialization and generalization are simple inversions of each other; they are represented in an E-R diagram in the same way.
- The terms specialization and generalization are used interchangeably.
- Can have multiple specializations of an entity set based on different features.
- E.g., permanent\_employee vs. temporary\_employee, in addition to instructor vs. secretary
- Each particular employee would be
  - a member of one of permanent\_employee or temporary\_employee,
  - and also a member of one of instructor, secretary
- The ISA relationship also referred to as **superclass subclass** relationship

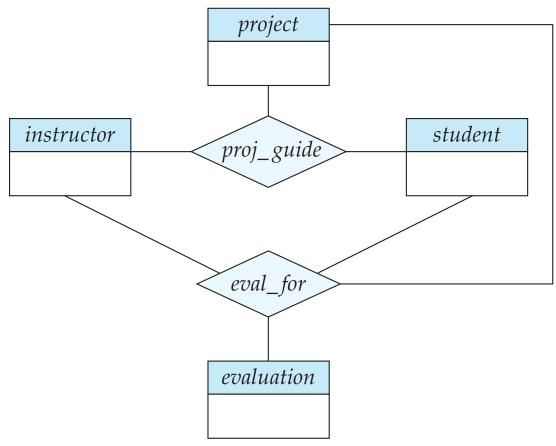

#### Design Constraints on a Specialization/ Generalization

- Constraint on which entities can be members of a given lower-level entity set.
  - condition-defined
    - Example: all customers over 65 years are members of *senior-citizen* entity set; *senior-citizen* ISA *person*.
  - user-defined
- Constraint on whether or not entities may belong to more than one lower-level entity set within a single generalization.
  - Disjoint
    - an entity can belong to only one lower-level entity set
    - Noted in E-R diagram by having multiple lower-level entity sets link to the same triangle
  - Overlapping
    - an entity can belong to more than one lower-level entity set
- **Completeness constraint** -- specifies whether or not an entity in the higher-level entity set must belong to at least one of the lower-level entity sets within a generalization.
  - total: an entity must belong to one of the lower-level entity sets
  - partial: an entity need not belong to one of the lower-level entity sets

#### **Aggregation**

- Consider the ternary relationship *proj\_guide*, which we saw earlier
- Suppose we want to record evaluations of a student by a guide on a project

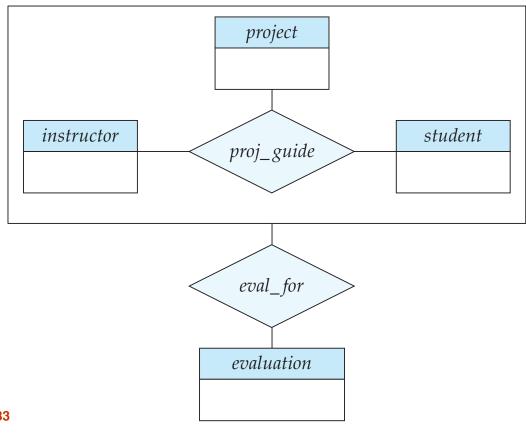

# **Aggregation (Cont.)**

- Relationship sets eval\_for and proj\_guide represent overlapping information
  - Every eval\_for relationship corresponds to a proj\_guide relationship
  - However, some proj\_guide relationships may not correspond to any eval\_for relationships
    - So we can't discard the proj\_guide relationship
- Eliminate this redundancy via aggregation
  - Treat relationship as an abstract entity
  - Allows relationships between relationships
  - Abstraction of relationship into new entity

# **Aggregation (Cont.)**

- Without introducing redundancy, the following diagram represents:
  - A student is guided by a particular instructor on a particular project
  - A student, instructor, project combination may have an associated evaluation

**NYU School of Engineering** 

## Representing Specialization as Schemas

#### Method 1:

- Form a schema for the higher-level entity
- Form a schema for each lower-level entity set, include primary key of higher-level entity set and local attributes

schema	attributes
person	ID, name, street, city
student	ID, tot_cred
employee	ID, salary

 Drawback: getting information about an employee requires accessing two relations, the one corresponding to the low-level schema and the one corresponding to the high-level schema

# Representing Specialization as Schemas (Cont.)

#### Method 2:

 Form a schema for each entity set with all local and inherited attributes

schema	attributes
person	ID, name, street, city
student	ID, name, street, city, tot_cred
employee	ID, name, street, city, salary

- If specialization is total, the schema for the generalized entity set (person) not required to store information
  - Can be defined as a "view" relation containing union of specialization relations
  - But explicit schema may still be needed for foreign key constraints
- Drawback: name, street and city may be stored redundantly for people who are both students and employees

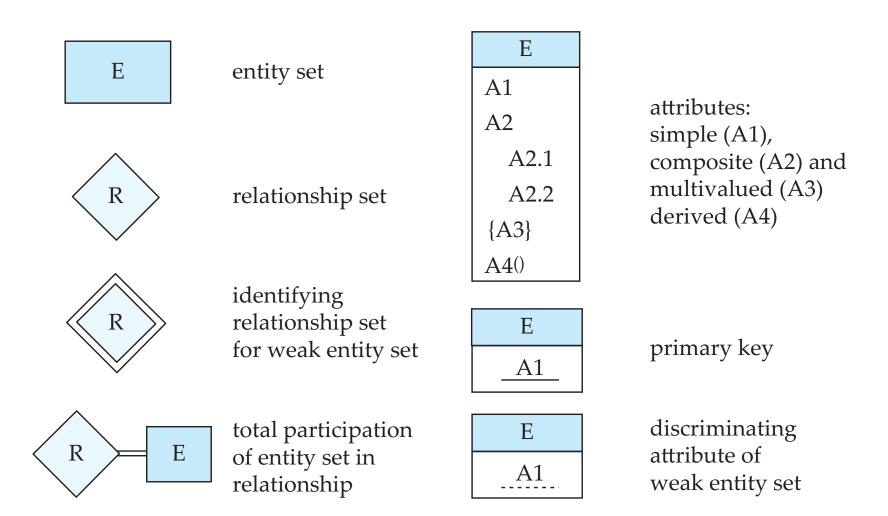

#### **E-R Design Decisions**

- The use of an attribute or entity set to represent an object.
- Whether a real-world concept is best expressed by an entity set or a relationship set.
- The use of a ternary relationship versus a pair of binary relationships.
- The use of a strong or weak entity set.
- The use of specialization/generalization contributes to modularity in the design.
- The use of aggregation can treat the aggregate entity set as a single unit without concern for the details of its internal structure.

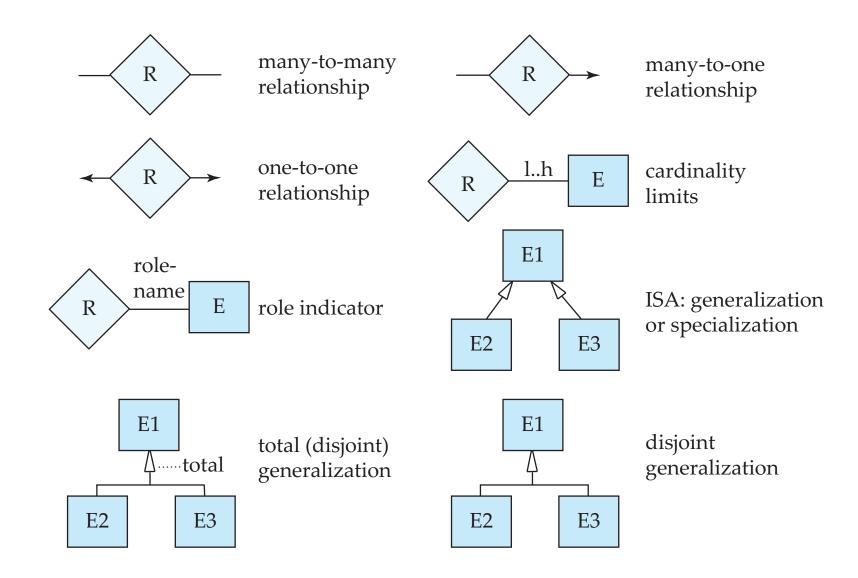

# **Summary of Symbols Used in E-R Notation**

# Symbols Used in E-R Notation (Cont.)

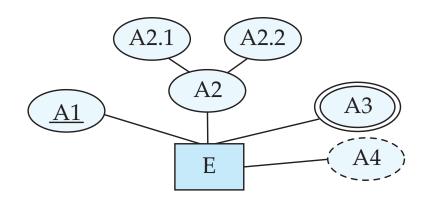

#### **Alternative ER Notations**

Chen, IDE1FX, ...

entity set E with simple attribute A1, composite attribute A2, multivalued attribute A3, derived attribute A4, and primary key A1

weak entity set

generalization

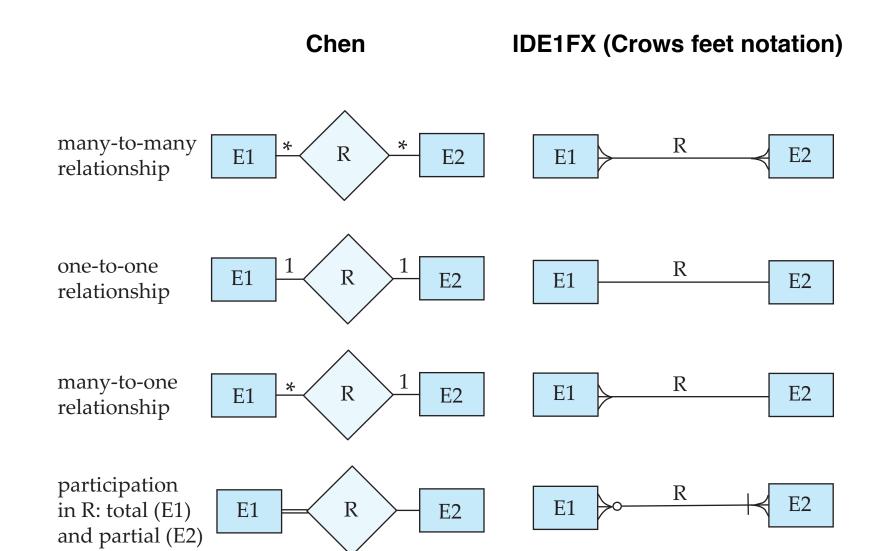

total generalization

#### Alternative ER Notations

#### **UML**

- UML: Unified Modeling Language
- UML has many components to graphically model different aspects of an entire software system
- UML Class Diagrams correspond to E-R Diagram, but several differences.
